Informally: What are CADs?

- A CAD provides an *explicit* representation of semi-algebraic sets, as opposed to the *implicit* representation provided by Tarski formulas.

- **Warning:** “CAD” refers to both a mathematical object and the data structure for representing that object. This dual usage can be confusing.

- **Definition:** For \( S \) a finite subset of \( \mathbb{R}[x_1, \ldots, x_n] \), the decomposition of \( \mathbb{R}^n \) into maximal connected regions in which the elements of \( S \) have invariant sign is called the *natural algebraic decomposition* defined by \( S \).

- **Definition:** The *level* of polynomial \( p \in \mathbb{R}[x_1, \ldots, x_n] \) is the largest \( k \) such that \( p \) has positive degree in \( x_k \).

The basic plan for CADs

Start with a Tarski formula $F$ defining a semi-algebraic set

1. Compute $P$, a projection factor set that contains the polynomials in $F$

2. Construct a CAD data structure from $P$

3. Annotate each sample point with the truth value of $F$ at that point

4. Depending on your problem ...
   
   (a) determine dimension, return an explicit point satisfying formula, etc., or
   (b) propagate truth values, simplify CAD, etc., and return defining Tarski
       formula for the set represented by the new CAD
